This interview on the subject of female genital cutting serves to contextualize a submission by Carlos D. Londoño Sulkin, who describes the changes of perception he and other members of the audience experienced after a lecture by Fuambai Ahmadu on this subject at the University of Regina on 19 March 2009. The title of Ahmadu’s talk was ‘Disputing the myth of the sexual dysfunction of circumcised women’. In order to make sense of Londoño Sulkin’s reactions to her account, Fuambai Ahmadu was invited to set out her case, which she does in the form of a question-and-answer session with Richard Shweder.

Richard Shweder: The voices of the many East and West African women who value the practice of genital modification for both girls and boys have not been audible in North American and European media accounts of the practice. How do you address the subject when you lecture on this topic?

Fuambai Ahmadu: I opened my talk at Regina with a short documentary film produced by my younger sister, Sunju Ahmadu, which depicted parts of the public celebrations of our own initiation/excision ceremony nearly two decades ago. The audience thoroughly engaged with the film and in the discussion that followed. I first talked about the film, addressing what I felt was the most obvious question in their minds: how could it be that the African women in the documentary spoke so positively about female initiation and excision (both referred to as bondo among the Kono and other ethnic groups in Sierra Leone)?

The Kono are a minority population who reside in the eastern part of Sierra Leone. This area became known worldwide as a result of the publicity surrounding the CNN documentary Cry Freetown and the Hollywood feature film Blood diamond that followed, which depicted the gruesome, protracted war in the country and its effect on Kono in particular because of the region’s high concentration of diamond deposits. The Kono, who are descendents of the Mande from what is now the area of Mali, practise female and male initiation and excision/circumcision as complementary and parallel cultural and symbolic processes celebrating the transition from boyhood to manhood and girlhood to womanhood respectively. Among many Kono, like perhaps most other Mande groups, there is a view of children as being part of nature, undefined and possessing both male and female elements. In male initiation rituals, the prepuce or foreskin of the penis symbolizes femininity and is associated with female sexual organs, thus removal of the foreskin represents the masculinization of the boy. In parallel and complementary form the exposed clitoris represents the male sexual organ or penis and thus its removal symbolizes the feminization of the girl child and marks her adult sexual status. In men’s ceremonies, men identify and celebrate their differences from women; similarly women’s ceremonies elaborate, exaggerate and celebrate their differences from men, often ridiculing and belittling male sexuality and supposed social and sexual superiority.

In Sierra Leone, women’s initiation is highly organized and hierarchical: the institution itself is synonymous with women’s power, their political, economic, reproductive and ritual spheres of influence. Excision, or removal of the external clitoral glans and labia minora, in initiation is a symbolic representation of patriarchal power. How can this be so? Removal of the external glans and hood is said to activate women’s ‘penis’ within the vagina (the clitoral ‘shaft’ and ‘g-spot’ that are subcutaneous). During vaginal intercourse, women say they dominate the male procreative tool (penis) and substance (semen) for sexual pleasure and reproductive purpose, but in ritual they claim to possess the phallus autonomously. Excision also symbolizes the ‘separation’ of mother and son or of matriarchy and patriarchy (in Mande mytholoogy matriarchy is portrayed as prior to and giving birth to patriarchy). Female elders say that initiation and the act of excision is a potent emotional and psychological reminder to men that it is women who give birth to them and mothers who, after God, are the natural origins or raw elements from which all human creation, culture and society are derived. This concept of a primordial, supreme and all-powerful Mother is at the core of Mande creation mythology and ritual practices that are prevalent even today.

Male circumcision reflects the other side of this duality, the separation of son from mother, phallos from owner, male from female. In men’s initiation it is not the phallos that is the dominant symbol of power, as in women’s rituals. It is the vagina itself and the obscurity of the womb that we see reflected in the secret ritual masks of the Mande male initiatory societies, as anthropologist Sara Brett-Smith (1997) aptly pointed out. It is through these symbolic means that Mande male ancestors learned the secrets and obtained ritual medicines that prepared them for warfare and hunting in the deep forests of the past. The dominant female substance that associates men with death is blood, and both menstrual and parturition blood in particular are imbued with awesome destructive powers.

So, contrary to much of the rhetoric of the anti-FGM campaigns, the female sex and female sexuality are not oppressed in, through or by these ritual practices. On the contrary, female sexuality and reproductive powers are celebrated and reified in the masquerades, as the origins of creation, of nature and of culture, and feared as potent weapons of death and destruction. This cultural and symbolic context of female initiation and excision explains how it could be that Kono girls and women in the film...
were speaking in positive, almost reverential terms, about the practice, their bodies and the experience of womanhood. There are different types of female genital cutting practices that are performed for many different reasons, and these practices prevail in diverse sociocultural contexts, so not all women who are affected necessarily support these practices or view them as empowering to girls and women.

RS: What is your general view of the relationships between informed anthropological and medical research on this topic and representations in the advocacy literature which describe the practice as ‘female genital mutilation’?

FA: The anthropological literature on this topic (prior to the nearly universal acceptance of the term FGM in the mid-1990s) was more nuanced and contextualized within the dominant socio-cultural frameworks of affected women. But what about the health risks? How could even well-meaning anthropologists justify the medical hazards of this practice and the sexual oppression of women as represented by advocacy groups who see culture in this instance as an excuse for male barbarism and domination? The problem with the representation of various forms of female circumcision as ‘mutilation’ is that the term, among other things, presupposes some irreversible and serious harm. This is not supported by current medical research on female circumcision.

Carla Obermeyer (1999, 2003), who was a consultant for WHO, published two comprehensive and critical reviews. The first looked at the available literature on female circumcision up to 1996, the second from 1997 to 2002. Her conclusion is as follows: ‘On the basis of the vast literature on the harmful effects of genital surgeries, one might have anticipated finding a wealth of studies that documents considerable increases in mortality and morbidity. This review could find no incontrovertible evidence of mortality, and the rate of medical complications suggests that they are the exception rather than the rule’ (Obermeyer 1999: 92).

Another major source, which contradicts received notions about the health hazards of excision in particular, is a study by Linda Morison et al. (2001) at the UK’s Medical Research Council Laboratories located in Fajara, The Gambia. Widely cited as authoritative in the literature, this research is the most systematic, comprehensive and controlled investigation of the health consequences of female circumcision yet to be conducted. In summary, the study found that the supposed morbidities often cited as common problems associated with excision (such as infertility, painful sex, vulval tumours, menstrual problems, incontinence and most endogenous infections) did not distinguish women who had the surgery from those who did not. The rate of infertility was exactly the same for both groups – 10%. The authors noted additionally that women expressed high levels of support for the practice.

However, neither Obermeyer’s reviews nor the Morison et al. study have been mentioned in any major Western press, despite their startling and counter-intuitive findings on female circumcision and health. This is in contrast to the highly publicized Lancet report by the WHO Study Group on FGM, released in June 2006, which received widespread, immediate and sensationalized press coverage highlighting claims about infant and maternal mortality during hospital birth. As Bettina Shell-Duncan (2008) pointed out, the New York Times unquestioningly sensationalized this group’s findings under the heading: ‘Genital cutting raises by 50% likelihood that mothers or their newborns will die, study finds’ (Rosenthal 2006). Shell-Duncan notes that what this shocking headline failed to mention is the modest magnitude of risk. Another observer noted that, in comparing risk factors in pregnancy, this places female circumcision somewhere behind maternal smoking.

I would note that in the extended New York Times Tierneylab blog‘ discussion of this topic you [Shweder] also questioned the findings of the WHO Lancet study and its purported evidence of increased ‘harm’ for circumcised women. You noted that the study collected data on women across six nations but never displayed the results for individual nations to see if they could be replicated; there was no direct control for the quality of health care available for ‘circumcised’ versus ‘uncircumcised’ women; the sample was unrepresentative of the whole population; and even given the evidence presented, any risk of genital surgery was astonishingly small and hardly a mandate for an eradication rather than a public health programme.

Sweden-based studies conducted by Birgitta Essen, an obstetrician, and by Sara Johnsdotter, a medical anthropologist, are worthy of mention (Johnsdotter and Essen 2004, Birgitta Essen et al. 2002, 2005). In Essen et al. 2002 no evidence was found of causal connection between genital surgeries and obstructed or prolonged labour. Essen et al. (2005) concluded, surprisingly, that circumcised women were at a lower risk of prolonged labour as compared with uncircumcised Swedish women.

Another obstetrician/gynaecologist, Crista Johnson (2008), who attends to a large number of Somali immigrant patients, has pointed out that the risk of still births may be particularly increased for circumcised women who delay prenatal care and getting to hospitals when they are experiencing complications because they fear being stigmatized by healthcare workers, and because these workers lack specialized knowledge of these women’s bodies. In other words, could it be the low standard of care circumcised women are receiving, and fears on the part of both affected women and healthcare providers in zero-tolerance and anti-FGM environments, that contribute to small differences in infant mortality rates in the Lancet study?

So, if women’s fears have been exaggerated and circumcised women rightly have their own fears about the risks of being uncircumcised, how can they justify excision of the very sensitive tissue that makes up the clitoris? As some concerned students have asked me, isn’t this tantamount to castration?

It has somehow become ubiquitous and obvious knowledge that female circumcision is intended to and actually does inhibit female sexual desire and feeling and that it is like cutting off the male penis, an analogy I never quite understood. But what is the research evidence on female circumcision and sexual pleasure? Obermeyer (1999:55) stated in her review that: ‘studies that systematically investigate the sexual feelings of women and men in societies where genital surgeries are found are rare, and the scant information available calls into question the assertion that female genital surgeries are fundamentally antithetical to women’s sexuality and incompatible with sexual enjoyment.’

However, neither Obermeyer’s reviews nor her own research in the Gambia (Ahmadu 2007), there are several important texts on this issue. The first paper was published by an ardent and vocal anti-FGM activist, Hanny Lightfoot-Klein, the author of Prisoners of ritual, a seminal work for anti-FGM advocates. In her article, Lightfoot-Klein (1989) challenges whether infibulation, the most extreme form of female circumcision, is inimical to women’s enjoyment of sex and experience of orgasm. According to her five-year research, 94% of circumcised women reported sexual satisfaction and orgasm and many said they had sex three or four times a week. So what was the problem for Lightfoot-Klein? Sudanese women, in her view, are completely subjugated by their husbands and have no authority whatsoever or agency over their own bodies. But I see a disturbing problem with the implications of this picture: how is that so-called mutilated African women are at one and the same time subjugated by
their husbands and also enjoying sex with these patriarchal oppressors and reaching orgasm several times per week?

Is it that African women are masochistic and disturbingly enjoy their own sexual subjugation? Or might this suggest that some Westerners and feminists have it wrong about the nature of African marriages, social systems and male-female interactions and intimacies? If the experiences of these Sudanese women are anything like my own and those of the community of women I was raised among, then I doubt very much that they are somehow sexually deviant masochists who are ignorant of and enjoy their own oppression.

Of particular interest is a recent publication by Lucrezia Catania (Catania et al. 2007), an Italian obstetrician and gynaecologist who runs a clinic with her Somali husband in Italy that is frequented by mainly Somali immigrants. According to the study, the findings ‘suggest, without doubt, that healthy “mutilated/circumcised” women who did not suffer grave long-term complications and who have a good and fulfilling relationship may enjoy sex and have no negative impact on psychosexual life (fantasies, desire and pleasure, ability to experience orgasm)’. Catania’s findings were also interesting in that, in comparison with her Italian control group, infibulated Somali women reported greater frequency of orgasms. These findings are very much in line with those of Lightfoot-Klein in her fieldwork with Sudanese women.

Kirsten Bell (2005) provides an interesting context for this debate by looking at changes in Western discourses on genital cutting and sexuality. In particular, she questions the current unspoken assumption that the male body provides the basis of understanding the female body. This is the assumption, Bell argues, that makes sense of how people readily, but in my view mistakenly, equate female circumcision with male castration.

In my own research in the Gambia and Sierra Leone (Ahmadu 2000, 2007), I have tried to point out the cultural and symbolic importance of gender complementarity and interdependence and the construction of heterosexual marriage and intercourse in understanding female and male initiation and excision/circumcision. For circumcised African women brought up in dual-sex (as opposed to male-dominated) cultures that celebrate male and female powers, heterosexual intercourse (rather than the presence of an external clitoris) is seen as key to women’s most intense, vaginally induced orgasms. Same-sex sexual interactions and relationships and ‘auto-sexuality’ exist and were largely ignored in the past as part of the realm of nature or childhood. Bondo women elders believe and teach that excision improves sexual pleasure by emphasizing orgasms reached through stimulation of the g-spot, which is said to be more intense and satisfying for an experienced woman. Excision of the protruding clitoris is said to aesthetically and physiologically enhance the appearance of the vulva and facilitate male-female coitus by removing any barrier to complete, full and deep penetration.

According to the women I interviewed, sexual foreplay is complex and requires more than immediate physical touch: emphasis is on learning erotic songs and sexually suggestive dance movements; cooking, feeding and feigned submission, as powerful aphrodisiacs, and the skills of aural sex (more than oral sex), are said to heighten sexual desire and anticipation. Orgasms experienced during vaginal intercourse, these female elders say, must be taught and trained, requiring both skill and experience on the part of both partners (male initiation ceremonies used to teach men sexual skills on how to ‘hit the spot’ in women – emphasizing body movement and rhythm in intercourse, and importantly, verbal innuendoes that titillate a woman’s senses). Thus, from the viewpoint of these women elders vaginal intercourse is associated with womanhood and adult female sexuality. In Mande cultures the emphasis is on the vagina as the source and symbol of womanhood or — to refer to Alice Walker’s popular anti-FGM novel — the hidden g-spot, rather than the visible protruding clitoris, is the ‘secret’ ‘joy’ adult women ‘possess’.

And it is the vagina that is the object of awe and difference in male initiation ceremonies. Male initiates (at least in the past) learn not to fear this powerful female sexual organ but rather how to manipulate it for their own and their partners’ pleasure and reproduction, as well as to obtain other secret powers of protection in hunting and warfare. Likewise female initiates are taught not to fear the male phallus but to dominate the penis for pleasure and semen in reproduction as well as in certain medicinal uses. Both male and female initiates, especially in the past, learn that sexual pleasure is not only an innate capacity in women but a right of all women in marriage. That a woman can be physiologically or psychologically incapable of
This essay is my reaction, as an outsider to ethnographic studies of genital modifications and of African peoples, to Fuambai Ahmadu’s discussion. Ahmadu commented that, paradoxically, an open discussion on her lecture would probably have been impossible at larger, more central institutions like the London School of Economics or New York University, where the issue would have generated too much disturbance.

Female genital cutting consists in the more or less ritualized incision or removal of part of the external genitalia of girls or young women. The cuts vary in form: in some versions the prepuce (hood) of the clitoris is pricked, in others the prepuce or the entire external part of the clitoris is removed. So-called ‘excisions’ involve the removal of the external part of the clitoris and the labia minora. The most famous but least practised version is infibulation (or Pharaonic circumcision), which involves removal of the labia minora and external part of the clitoris and sewing the labia majora together, leaving a small orifice for urination and menstruation. Genital modifications of these and similar kinds are widely practised in sub-Saharan Africa and in a few other societies through history and around the world. In the literature and the media, the practice is often represented as a brutal violation of little girls’ rights to bodily and sexual integrity, often by domineering patriarchs and brainwashed matriarchs, all in the service of male domination over women’s bodies and sexuality. A common term for the practice builds in this sense of damage done to the women in question: it is called female genital mutilation (FGM). Presented thus, opposition to FGM appears to be a safe, no-brainer ethical cause, and signing a zero-tolerance-to-FGM petition unproblematic. What monster wouldn’t support it, and protect women from mutilation and a life of poor health and joyless sex?”

Many – including some scholars with direct and nuanced expertise on the matter – find that FGM is where one draws the line. Of course, I find this view patronizing and infantilizing of adult African women who, like Western women who opt for cosmetic genital surgeries, should be free to decide for themselves what to do with their own bodies.

Another point I made that Goldberg overlooked is that supporters of female circumcision justify the practice on much of the same grounds that they support male circumcision. The uncircumcised clitoris and penis are considered homologous aesthetically and hygienically. Just as the male foreskin covers the head of the penis, the female foreskin covers the clitoral glans. Both, they argue, lead to build-up of smegma and bacteria in the layers of skin between the hood and glans. This accumulation is thought of as odorous, susceptible to infection and a nuisance to keep clean on a daily basis. Further, circumcised women point to the risks of painful clitoral adhesions that occur in girls and women who do not cleanse properly, and to the requirement of excision as a treatment for these extreme cases. Supporters of female circumcision also point to the risk of clitoral hypertrophy or an enlarged clitoris that resembles a small penis. For these reasons many circumcised women view the decision to circumcise their daughters as something as obvious as the decision to circumcise sons: why, one woman asked, would any reasonable mother want to burden her daughter with excess clitoral and labial tissue that is unhygienic, unsightly and interferes with sexual penetration, especially if the same mother would choose circumcision to ensure healthy and aesthetically appealing genitalia for her son?

I write and teach about different cultural perspectives on female circumcision with regard to pleasure, hygiene and genital aesthetics, not to insist that uncircumcised Western women opponents have it wrong and circumcised African women proponents are right (such stereotypical categorizations are never quite so neat anyway) but to point out that there are multiple and contested views and experiences and that no one is more right than the other. So it is my opinion that we need to remove the stigma of mutilation and let all girls know they are beautiful and accepted, no matter what the appearance of their genitalia or their cultural background, lest the myth of sexual dysfunction in circumcised women become a true self-fulfilling prophecy, as Catania and others are increasingly witnessing in their care of circumcised African girls and women.

Anthropology, liberalism and female genital cutting

1. See the WHO (2008) interagency statement for a recent and succinct call to bring cutting practices to an end. 2. For a discussion of such calls among anthropologists, see Hernlund and Shell-Duncan (2007) and Shwedder (2002); examples of expert critiques are Mandara, Abusharaf and Mackie in Shell-Duncan and Hernlund (2000). 3. I use the term ‘irony’ here more or less in Rorty’s sense, to refer Hernlund and Shell-Duncan (2000) and the contingent of the contingency of one’s central beliefs and desires (1989: xv); I would add that it would involve acknowledging charitably that others might for understandable causes or reasons not share them. 4. I am neutral about the disappearance or further spread of cutting practices as I am about tattooing and tooth braces: let these feature in people’s symbolic practices constitutive of personhood, as long as they are not too extreme. If they were to disappear, let it not be as a result of impositions from powerful outsiders with unquestioning faith in their own understandings of personhood, cosmology and society.

— 2005. No association between female circumcision and prolonged labor: A case control study of immigrant women having birth in Sweden. European Journal of Obstetrics and Gynecology and make both men and women more judicious about everything, including sex. I would also underscore that acts of genital cutting – male or female – are symbolic gestures, and as such their associations and meanings are multiple and changing; nothing ties them intrinsically to a particular religion or context of gender roles (for surprising examples, see Thomas 2000 and Leonard 2000).

The gist of the most subtly and innocently ethnocentric question I heard anyone pose to Ahmadu was the following: even if perhaps there weren’t great health risks, and even if perhaps it isn’t fundamentally a practice of male domination over women, why bother to undergo the often painful procedure, or reproduce it in younger generations, when nature has given women bodies endowed with whole clitorides, the better suited for enjoyment and sex? In other words, why on earth would people do this to themselves or their daughters? Wouldn’t it be simpler and more conducive to well-being and happiness not to indulge in cutting? This question took for granted that our (Euroamerican) societies’ mainstream accounts, practices and aesthetic preferences concerning our genders, bodies and sex are somehow more natural or normal or better than those of people whose views of these matters differ from ours. (For a deep and nuanced explanation of this, see Boddy in Hernlund and Shell-Duncan 2007.) For instance, according to Ahmadu, Kono men and women find circumcision generally cleaner and nicer-looking, and uncircumcised genitals immature and prone to stink and itch. In other words, the idea of the ‘natural’ body as an ideal of beauty and wholesomeness does not hold sway with them.

It really doesn’t hold sway with EuroAmericans, either: depending on our gender, we pierce our bodies, tattoo them, cut or colour our hair, shave our faces or armpits, develop hypertrophic muscles, and so forth, but we reveal our bias when we treat these practices as less artificial than the ones of one’s own society.

For Kono women, to undergo bondo – the initiation ritual that involves excision – makes them a kind of person that is admirable: informed, courageous, capable of dealing with pain, mature and womanly. Is making the altered form of one’s genitals such a significant symbol of one’s personal virtues a very particular or parochial feature of this society? Sure. But so is everything we do in North America and Europe to our bodies to be clean-cut, or authentic, or cool, or beautiful, or elegant, or healthy. Furthermore, bondo establishes age-group and other relationships among the different women involved, relationships that Kono women and men value greatly. Are the kinds of relationships created through the Kono’s excision rituals particular to that society, and thus to some extent insular? Maybe. But so are our relationships with each other and the ways we go about establishing them. We still deeply value our relationships and the symbolic mechanisms by which we create them. So do Kono and other people.

My own sense, after listening to Ahmadu, is that many EuroAmericans’ reactions to the removal of any genital flesh is shaped by parochial understandings and perfectly contestable biases and values concerning bodies, gender, sex and pain. Their arbitrariness becomes clear in the combined light of some clinical research and Ahmadu’s (2007) and Shwedder’s (2002) point that there is very little Western protest against what could be portrayed as male genital mutilation, namely circumcision. Many Westerners find it easy to buy into the ‘fact’ that it is a salutary, hygienic and even aesthetically pleasing practice in our societies, or at least an unproblematic one, but do not so easily buy it when Kono women say the same about female circumcision.

A discussion that came up at Ahmadu’s talk concerned whether girls consented freely to being excised. Did they know what was going to happen to them? If they knew, but knew as well that they risked being denigrated, ostracized and prolonged the line on multiculturalism, relativism and tolerance, and deem it important to work to end these practices. It was Ahmadu’s (2000) paper that led me to think differently about cutting practices and movements to eradicate them. It reminded me of certain discussions about threats to liberal- ism. The philosopher Richard Rorty (1989), citing Judith Shklar, defined liberals as people who think that the worst thing one can be is cruel; reducing cruelty is one of the good things we’re about when we seek knowledge and generate change. That same interest motivates many a philanthropic cause. But liberal achievements and causes – those that seek to increase our freedoms and reduce our cruelties – run the risk of becoming simplistic and sclerotic. Without some ironic awareness that our preferences and convictions, even if we are willing to fight for them, are a function of the contingencies of our biographies, our causes can become coarse and battering rams with no consideration for different points of view or room for subtlety, and may therefore start perpe-

trating their own cruelties. I find this to be the case with movements seeking to eradicate female genital cutting.

Ironic self-criticism seems to me to be necessary for Westerners thinking about cutting. Both knee-jerk reactions (‘it’s wrong because it’s wrong!’) and some more thoughtful ones take for granted that something indubi-
and rejected as potential spouses if they did not submit to cutting, were they truly ‘free’ to decide? Would it even be ethical to allow little girls to make such ‘radical’ decisions about their bodies? Ahmadu had several points to make. One was that Kono girls in this day and age know well that in bondo they will undergo a surgical procedure, that it’s ‘down there’, and that for some it will be excruciating. However, for most of them – even when there is pain and fear – the event as a whole is a very positive and rewarding experience, and they engage animatedly with it. As for adults making the decision to have their daughters circumcised, it is so different from us forcing a child to undergo the inconvenience and pain of putting bracaces on to straighten their teeth? In both cases, parents and experts feel it is a healthy practice that enhances aesthetics, and that it is done for the child’s benefit.

Other questions concerning freedom inevitably come up here. Some cannot imagine a woman giving away quite any portion of her genital flesh, and so insist that this has to be a case of brainwashing. Ahmadu is suspicious of the notion of freedom behind this question, as am I. We are not overarchingly clairvoyant subjects, choosing from a metaposition the virtues and values that appeal to us: most of these are the product of our upbringing. We don’t freely choose, in this day and age in North America, to find that little bodies are beautiful. Most of us just do. Had we been born among Arabs in Nigeria or in Hawaii 50 years ago, most of us would probably find, respectively, very chubby women and men to be much more appealing than thin ones. Many of us do not have the sense that we choose to find that a person kicking a dog is being cruel, or that a political demonstrator lying down in front of an army tank is courageous: we just see that they are. But such moral evaluations, however apparently spontaneous, stem from an acquired moral sense likely to differ from those of our ancestors or of other cultural groups; we therefore not share our evaluations. So perhaps Kono girls do not ‘freely’ choose to find it admirable to face the cutting courageously, or to find modified vulvas prettier than ones with ‘cutting’ clitiorides and prepuces. They just do. Of course, this can change (as can our moral outrage).

So what are the inadvertent cruelties that zero-tolerance-to-FGM approaches perpetrate? Catania’s work suggests that physicians may buy into non-scientific biases concerning female genital cutting, misdiagnose excision as the source of any sexual and reproductive tribulations a patient may report, and as a result not provide proper treatment for other real causes. Anti-FGM lobbying has succeeded in making cutting illegal in several countries; there, circumcised women may postpone visits to medical personnel out of fear of stigmatization or prosecution, and thus risk the exacerbation of their gynaecological problems. Some anti-FGM activism has also rejected any medicalization of the practice – that is, any provision of biomedical equipment, drugs, spaces and training to circumcisers, or any sanctioning of physicians and nurses to practise cutting – lest it legitimize the practice in any way. Access to medical technology would, however, go far towards protecting women from the occasional medical woes stemming from cutting (see Hernlund and Shell-Duncan 2007).

However, what most took me aback after hearing Ahmadu and watching her sister’s video with footage of public aspects of their own ceremony and interviews with circumcised and uncircumcised women, was the inquiet of discourses that suggest to bubble, sexy Kono women (women who in no uncertain terms express a delight in sex and report great satisfaction with it) that they are mutilated and do not in fact achieve orgasm. Such discourses can function as persuasive, self-fulfilling prophecies, and it is not surprising that many circumcised women in diaspora come to think of themselves as mutilated and their circumcision rituals as necessarily traumatizing violations, and to blame sexual troubles on their modifications.

Anthropological and other social scientific empirical research on the nitty-gritty of everyday talk and other aspects of social life – like Fuambilik Ahmadu’s studies of understandings and practices of excision – are particularly well suited to make edifying contributions to liberal causes. Many anthropologists, reacting against collectivist social theories and some of the less felicitous entailments of cultural relativism, have joined in the condemnation of female circumcision without first taking counsel from our discipline’s methodological requirement actually to pay attention to what the people we write about say and do about this or that, over an extended period. Listening to Ahmadu, I can no longer condemn the practices of genital cutting in general, nor would I be willing to sign a zero-tolerance contract on the matter of bonding. I tolerate the possibility of Kono girls not undergoing bondo as an important symbolic gesture that enabled her to relate in a way she valued to various groups of women in her Kono community. I find beauty in her description of the supportive relationships that bondo generates among Kono women. These are generative of gendered relations, of course, but not necessarily egregious ones. I also admire Ahmadu’s and other Kono women’s physical courage. Doubtless in some cases excision is cruel, it’s meanings and health implications less positive for the individuals involved than Ahmadu describes for the Kono, or the power relations involved injurious; let liberal campaigners engage vigorously with patterns in those cases, with detailed empirical research that is willing to question its own premises, rather than by means of an illiberal, scorched-earth proscription of excision.
